Question assigned to the following page: [1](#)

# HOMEWORK-3 | MATH 541A

Problem 1: Suppose  $y_i \in \mathbb{N}$  and  $x_i \in \mathbb{R}$ . Assume  $y_i$  are independent Poisson random variables such that  $P(y_i | x_i) = \frac{e^{-\lambda_i} \lambda_i^{y_i}}{y_i!}$  where  $\lambda_i > 0$ .

MLE for Poisson Regression } Let  $n_i = \ln \lambda_i$  and assume  $n_i = \langle x_i, \theta \rangle$

1. Write the pmf  $P(y_i | \lambda_i)$  in an exponential form.

Soln:  $P(y | \lambda) = \frac{1}{y!} \exp\{-\lambda\} \lambda^y$ . Since  $n = \ln \lambda$ ,  $\lambda = e^n$ .

$$\therefore P(y | \lambda) = \frac{1}{y!} \exp\{-e^n\} e^{ny} = \frac{1}{y!} \exp\{ny - e^n\}$$

$$\therefore P(y | \lambda) = h(y) \exp\{n \cdot T - A(n)\} \text{ where } h(y) = \frac{1}{y!}, A(n) = e^n$$

$T(y) = y$  and  $A(n) = e^n$ .

2. Given  $n$  independent data  $(x_1, y_1), \dots, (x_n, y_n)$ , write down the likelihood function  $L(\theta | x_1, y_1, \dots, x_n, y_n)$ .

Soln: Recall that  $n = \ln \lambda = \langle n, \theta \rangle$  which implies  $\lambda = e^{\langle n, \theta \rangle}$

$$L(\theta) := L(\theta | x_1, y_1, x_2, y_2, \dots, x_n, y_n) = p(x_1, y_1, x_2, y_2, \dots, x_n, y_n | \theta)$$

$$L(\theta) = p(x_1, y_1 | \theta) \cdot p(x_2, y_2 | \theta) \cdots p(x_n, y_n | \theta).$$

$$p(x, y | \theta) = p(y | x, \theta) \cdot p(x | \theta) = p(y | \lambda) \cdot p(x | \theta).$$

As data is independent of  $n$  (hence  $\theta$ ),  $p(x | \theta) = p(x)$ .

$$\therefore p(x, y | \theta) = p(y | \lambda) \cdot p(x | \theta) = p(y | \lambda) p(x).$$

$$\Rightarrow p(x_1, y_1 | \theta) \cdots p(x_n, y_n | \theta) = p(y_1 | \lambda_1) \cdots p(y_n | \lambda_n) \cdot \prod_{i=1}^n p(x_i)$$

$$\Rightarrow \prod_{i=1}^n p(x_i, y_i | \theta) = \prod_{i=1}^n p(y_i | \lambda_i) \cdot \prod_{i=1}^n p(x_i)$$

$$\Rightarrow L(\theta) = \underbrace{\prod_{i=1}^n h(y_i)}_{H(y)} \cdot \exp\left\{\sum_{i=1}^n n_i y_i - \sum_{i=1}^n e^{n_i}\right\} \underbrace{\prod_{i=1}^n p(x_i)}_{G(x)}$$

$$\Rightarrow L(\theta) = H(y) G(x) \exp\left\{\sum_{i=1}^n [n_i y_i - e^{n_i}]\right\}$$

$$\Rightarrow L(\theta) = H(y) G(x) \exp\left\{\sum_{i=1}^n [\langle x_i, \theta \rangle y_i - e^{\langle x_i, \theta \rangle}]\right\}$$

Questions assigned to the following page: [1](#) and [2](#)

3. Write the MLE for  $\theta$  as a solution to an optimization problem.

$$\begin{aligned} \text{Soln: } \hat{\theta}_{\text{MLE}} &= \underset{\theta}{\operatorname{argmax}} L(\theta) \\ &= \underset{\theta}{\operatorname{argmax}} H(y) G(x) \exp \left\{ \sum_{i=1}^n [\langle x_i, \theta \rangle y_i - e^{\langle x_i, \theta \rangle}] \right\} \\ &= \underset{\theta}{\operatorname{argmax}} \exp \left\{ \sum_{i=1}^n [\langle x_i, \theta \rangle y_i - e^{\langle x_i, \theta \rangle}] \right\} \end{aligned}$$

Problem 2: Consider the following questions:

Bayesian  
Estimator

1. Assume  $x_1, x_2, \dots, x_n$  are sampled i.i.d. from Poisson( $\lambda$ )

a) Find the conjugacy family for a Poisson( $\lambda$ ) distribution.

Soln: We know from the lecture notes that the conjugacy family of Poisson distribution is  $\lambda \sim \text{Gamma}(\alpha, \beta)$ , i.e. a Gamma distribution

$$f(\lambda | \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} \lambda^{\alpha-1} e^{-\beta\lambda}, \quad \lambda > 0, \alpha, \beta >$$

b) Assuming the prior of  $\lambda$  is from the conjugacy family, compute the posterior distribution.

Let  $x \sim \text{Poisson}(\lambda)$  and the prior be  $\lambda \sim \text{Gamma}(\alpha, \beta)$

$$f(x|\lambda) = \frac{\lambda^x e^{-\lambda}}{x!} \quad f(\lambda | \alpha, \beta) = \frac{\beta^\alpha \lambda^{\alpha-1} e^{-\beta\lambda}}{\Gamma(\alpha)}$$

$$\text{posterior} = f(\lambda | \vec{x}) \propto f(\vec{x} | \lambda) f(\lambda)$$

$$\begin{aligned} \Rightarrow f(\lambda | \vec{x}) &\propto \lambda^{\sum x_i} e^{-\lambda n} \cdot \lambda^{\alpha-1} e^{-\beta\lambda} \\ &\propto \underbrace{\lambda^{\sum x_i + \alpha - 1} \cdot e^{-\lambda(\beta+n)}}_{\text{Gamma}(\sum_{i=1}^n x_i + \alpha - 1, \beta + n)} \end{aligned}$$

c) Compute the posterior mean and the MAP estimators for  $\lambda$ .

Soln: Since the mean of  $\text{Gamma}(\alpha, \beta)$  is  $\alpha/\beta$ , the posterior mean estimate is  $\bar{\lambda} = \frac{\sum x_i + \alpha}{\beta + n}$

$$\text{The MAP estimate is } \hat{\lambda}_{\text{MAP}} = \underset{\lambda}{\operatorname{argmax}} f(\lambda | \vec{x}) = \underset{\lambda}{\operatorname{argmax}} \lambda^{\sum x_i + \alpha - 1} \cdot e^{-\lambda(\beta+n)}$$

$$\therefore \hat{\lambda}_{\text{MAP}} = \underset{\lambda}{\operatorname{argmax}} \lambda^{\sum x_i + \alpha - 1} \cdot e^{-\lambda(\beta+n)} = \underset{\lambda}{\operatorname{argmax}} \text{Gamma}(\sum x_i + \alpha, \beta + n)$$

Since the mode of a Gamma distribution is  $\frac{\alpha-1}{\beta}$  and MAP gives us this mode,  $\hat{\lambda}_{\text{MAP}} = \frac{(\sum x_i + \alpha - 1) - 1}{\beta + n} = \frac{\sum x_i + \alpha - 2}{\beta + n}$

Question assigned to the following page: [2](#)

2. Let  $x_1, \dots, x_n$  be iid samples from  $N(\theta, \sigma^2)$  where  $\sigma^2$  is a known constant. Let the prior distribution of  $\theta$  be a Laplace distribution, that is,  $\pi(\theta) = \frac{1}{2a} e^{-|\theta|/a}$ ,

where  $a$  is a known constant. Note that in this case, the prior distribution is not from the Conjugacy family.

a) Find the posterior distribution  $\pi(\theta | x_1, \dots, x_n)$ .

Soln:  $x \sim N(\theta, \sigma^2)$  and  $\theta \sim \pi(\theta)$

$$\begin{aligned}\text{posterior} &= \pi(\theta | x_1, \dots, x_n) = f(x_1, \dots, x_n | \theta) \cdot \pi(\theta) \\ &= \prod_{i=1}^n \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{(x_i - \theta)^2}{2\sigma^2}\right\} \cdot \frac{1}{2a} \exp\left\{-\frac{|\theta|}{a}\right\} \\ &= \left[\frac{1}{2\pi\sigma^2}\right]^n \exp\left\{-\frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \theta)^2\right\} \cdot \frac{1}{2a} \exp\left\{-\frac{|\theta|}{a}\right\} \\ &= \frac{1}{2a} \cdot \left[\frac{1}{2\pi\sigma^2}\right]^n \exp\left\{-\frac{1}{2} \left( \frac{1}{\sigma^2} \sum_{i=1}^n (x_i - \theta)^2 + \frac{|\theta|}{a} \right)\right\}\end{aligned}$$

This distribution, the posterior, seems to be from exponential family.

Simplifying further,

$$\begin{aligned}\pi(\theta | x_1, x_2, x_3, \dots, x_n) &\propto \exp\left\{-\frac{1}{2} \left( \frac{1}{\sigma^2} \sum (x_i - \theta)^2 + \frac{|\theta|}{a} \right)\right\} \\ \Rightarrow \pi(\theta | x_1, \dots, x_n) &\propto \exp\left\{-\frac{1}{2} \left( \frac{1}{\sigma^2} [\sum x_i^2 + n\theta^2 - 2\theta \sum x_i] + \frac{|\theta|}{a} \right)\right\} \\ &\propto \exp\left\{-\frac{1}{2\sigma^2} \cdot \sum x_i^2\right\} \exp\left\{-\frac{1}{2} \left( \frac{1}{\sigma^2} [n\theta^2 - 2\theta \sum x_i] - \frac{|\theta|}{a} \right)\right\} \\ &\propto \exp\left\{-\frac{1}{2} \left( \frac{n\theta^2 - 2\theta \sum x_i}{\sigma^2} - \frac{|\theta|}{a} \right)\right\} \\ &\propto \exp\left\{-\frac{n\theta^2 + 2\theta \sum x_i}{2\sigma^2}\right\} \cdot \exp\left\{-\frac{|\theta|}{a}\right\}\end{aligned}$$

The posterior's mean can be computed as  $\bar{\theta} = \int_{-\infty}^{\infty} \theta \pi(\theta | x_1, \dots, x_n) d\theta$ . This would be the posterior mean estimate. I am not sure if there is a closed form value of this integral but one can always use numerical methods.

Question assigned to the following page: [2](#)

For the MAP estimate,  $\hat{\theta}_{\text{MAP}} = \underset{\theta}{\operatorname{argmax}} \Pi(\theta | x_1, \dots, x_n)$

$$\Rightarrow \hat{\theta}_{\text{MAP}} = \underset{\theta}{\operatorname{argmax}} \exp \left\{ \frac{1}{2} \left( -\frac{n\theta^2 + 2\theta \sum x_i}{\sigma^2} + \frac{2|\theta|}{a} \right) \right\}$$

$$= \underset{\theta}{\operatorname{argmax}} \left( \frac{2\theta \sum x_i - n\theta^2}{\sigma^2} + \frac{2|\theta|}{a} \right)$$

$$= \underset{\theta}{\operatorname{argmax}} \left( \frac{n\theta [2\bar{x} - \theta]}{\sigma^2} + \frac{2|\theta|}{a} \right), \quad \bar{x} := \frac{\sum x_i}{n}$$

$$\text{Let } g(\theta) = \left[ \frac{n\theta [2\bar{x} - \theta]}{\sigma^2} + \frac{2|\theta|}{a} \right]$$

$$g'(\theta) = \left[ \frac{n}{\sigma^2} (-\theta + 2\bar{x} - \theta) + \frac{2}{a} \operatorname{sgn}(\theta) \right]$$

where  $\operatorname{sgn}(\theta) = \begin{cases} 1, & \theta > 0 \\ -1, & \theta \leq 0 \end{cases}$

$$\Rightarrow g'(\theta) = \left[ \frac{n}{\sigma^2} (-2\theta + 2\bar{x}) + \frac{2}{a} \operatorname{sgn}(\theta) \right]$$

Setting this derivative to zero,

$$g'(\theta) = 0 = \frac{n}{\sigma^2} (\bar{x} - \theta) + \frac{2}{a} \operatorname{sgn}(\theta)$$

$$\Rightarrow \frac{n}{\sigma^2} (\bar{x} - \theta) = -\frac{1}{a} \operatorname{sgn}(\theta)$$

Since  $\operatorname{sgn}(\theta) \neq 0 \neq \theta$ , we can multiply both sides by  $\operatorname{sgn}(\theta)$ .

$$\Rightarrow \frac{n}{\sigma^2} (\bar{x} - \theta) \operatorname{sgn}(\theta) = -\frac{1}{a} \underbrace{\operatorname{sgn}^2(\theta)}_{+1} = -\frac{1}{a}$$

$$\Rightarrow \frac{an}{\sigma^2} (\bar{x} - \theta) \operatorname{sgn}(\theta) = -1$$

$$\Rightarrow \frac{an}{\sigma^2} (\bar{x} - \theta) \operatorname{sgn}(\theta) + 1 = 0$$

$$\Rightarrow (\bar{x} - \theta) \operatorname{sgn}(\theta) = -\frac{\sigma^2}{na}$$

For  $\theta > 0$ ,  $\theta_1 = \bar{x} + \frac{\sigma^2}{na}$  & for  $\theta < 0$ ,  $\theta_2 = \bar{x} - \frac{\sigma^2}{na}$ .

We will need to check at which of these points  $g(\theta)$  is maximized.

$$\text{i.e. } \hat{\theta}_{\text{MLE}} = \underset{\theta \in \{\theta_1, \theta_2\}}{\operatorname{argmax}} g(\theta)$$

Question assigned to the following page: [3](#)

Problem 3: The following questions are from textbook.

1. Let  $x_1, \dots, x_n$  be i.i.d random variables with the probability density function  $f(x|\theta)$ , where if  $\theta=0$ , then

$$f(x|\theta) = \begin{cases} 1, & \text{if } 0 < x < 1 \\ 0, & \text{otherwise} \end{cases}$$

while if  $\theta=1$ , then

$$f(x|\theta) = \begin{cases} \frac{1}{2\sqrt{x}}, & \text{if } 0 < x < 1 \\ 0, & \text{otherwise} \end{cases}$$

Find the MLE of  $\theta$ .

Sol<sup>n</sup>: We only know  $f(x|\theta)$  when  $\theta=0$  or  $\theta=1$ . So we can only say if  $\theta=0$  or  $\theta=1$  maximizes <sup>Likelihood of</sup> some given sample  $x_1, \dots, x_n$ .

$$L(\theta|\vec{x}) = f(\vec{x}|\theta) = \prod_{i=1}^n f(x_i|\theta)$$

Let us try to represent  $f(x|\theta)$  in a single expression instead of the piecewise definition.  $f(x|\theta) = \sum_{x \in \{0,1\}} \left[ \mathbb{I}_{\{\theta=0\}} + \frac{1}{2\sqrt{x}} \mathbb{I}_{\{\theta=1\}} \right]$  indicates fn.

When any one of  $x_i$  lies outside  $(0,1)$ , we get  $L(\theta|\vec{x})=0$  for both  $\theta=0$  &  $\theta=1$ . Hence both are equally likely. We could break tie and pick any one in this situation.

When all  $x_i$  are in the interval  $(0,1)$ , then

$$f(x|\theta) = \mathbb{I}_{\{\theta=0\}} + \frac{1}{2\sqrt{x}} \mathbb{I}_{\{\theta=1\}}$$

Notice that  $\mathbb{I}_{\{\theta=0\}} \mathbb{I}_{\{\theta=1\}} = 0$  as  $\theta$  cannot be 0 & 1 at the same time.

$$\therefore L(\theta|\vec{x}) = \prod_{i=1}^n f(x_i|\theta) = \prod_{i=1}^n \left[ \mathbb{I}_{\{\theta=0\}} + \frac{1}{2\sqrt{x_i}} \mathbb{I}_{\{\theta=1\}} \right]$$

$$= \prod_{i=1}^n \mathbb{I}_{\{\theta=0\}} + \prod_{i=1}^n \left( \frac{1}{2\sqrt{x_i}} \mathbb{I}_{\{\theta=1\}} \right)$$

(this happens because the cross terms contain  $\mathbb{I}_{\{\theta=0\}} \cdot \mathbb{I}_{\{\theta=1\}}$  and hence go to zero.)

Question assigned to the following page: [3](#)

$$\begin{aligned}
L(\theta|x) &= \prod_{i=1}^n \mathbb{I}_{\{\theta=0\}} + \prod_{i=1}^n \frac{1}{2\sqrt{x_i}} \mathbb{I}_{\{\theta=1\}} \\
&= \underbrace{\mathbb{I}_{\{\theta=0\}}}_{\text{II}_{\{\theta=0\}}} + \left( \prod_{i=1}^n \frac{1}{2\sqrt{x_i}} \right) \left( \prod_{i=1}^n \mathbb{I}_{\{\theta=1\}} \right) \\
&= \underbrace{\mathbb{I}_{\{\theta=0\}}}_{\text{II}_{\{\theta=0\}}} + \left( \prod_{i=1}^n \mathbb{I}_{\{\theta=1\}} \right) \left( \prod_{i=1}^n \frac{1}{2\sqrt{x_i}} \right) \\
&= \underbrace{\mathbb{I}_{\{\theta=0\}}}_{\text{II}_{\{\theta=0\}}} + \underbrace{\mathbb{I}_{\{\theta=1\}}}_{\text{II}_{\{\theta=1\}}} \left( \prod_{i=1}^n \frac{1}{2\sqrt{x_i}} \right) \\
&= \underbrace{1 \cdot \mathbb{I}_{\{\theta=0\}}}_{A} + \underbrace{\mathbb{I}_{\{\theta=1\}}}_{B} \left( \prod_{i=1}^n \frac{1}{2\sqrt{x_i}} \right) = \underbrace{A \mathbb{I}_{\{\theta=0\}}}_{1} + B \mathbb{I}_{\{\theta=1\}}
\end{aligned}$$

Note: If  $g(z) = a \mathbb{I}_{\{z=z_1\}} + b \mathbb{I}_{\{z=z_2\}}$ ,

$$\text{then } \operatorname{argmax}_z g(z) = \begin{cases} z_1, & a > b \\ z_2, & a < b \end{cases}$$

$$\begin{aligned}
\text{i.e. } \operatorname{argmax}_z g(z) &= z_1 \mathbb{I}_{\{a>b\}} + z_2 \mathbb{I}_{\{b>a\}} \\
&= z_1 \mathbb{I}_{\{a>b\}} + (1 - \mathbb{I}_{\{a>b\}}) z_2 \\
&= z_2 + (z_1 - z_2) \mathbb{I}_{\{a>b\}}
\end{aligned}$$

Also note that in this case, we are dealing with  $x_i \in (0,1)$  as for the case where  $\exists x_i \notin (0,1)$ , we mentioned that there is a tie bet'n  $\theta=0$  &  $\theta=1$  & any one of them is a good NLE estimate.

$$0 < x_i < 1 \Rightarrow 0 < \sqrt{x_i} < 1 \Rightarrow 1 < \frac{1}{\sqrt{x_i}} < \infty$$

$$\text{or } 1 < \frac{1}{\sqrt{x_i}}$$

$$\therefore \underbrace{\prod_{i=1}^n \frac{1}{\sqrt{x_i}}}_{B} > \underbrace{\frac{1}{A}}_{A} \Rightarrow B > A = 1 > 0$$

$$\therefore \hat{\theta}_{MLE} = \operatorname{argmax}_{\theta} L(\theta|x) = \operatorname{argmax}_{\theta} A \mathbb{I}_{\{\theta=0\}} + B \mathbb{I}_{\{\theta=1\}} = 1$$

$$\therefore \hat{\theta}_{MLE} = \begin{cases} 0 & ; \quad \exists x_i \notin (0,1) \\ 1 & ; \quad \forall x_i \in (0,1) \end{cases}$$

Question assigned to the following page: [3](#)

- d. Let  $x_1, \dots, x_n$  be iid random variables with distribution  $N(\theta, \sigma^2)$  and suppose the parameter  $\theta$  is random with a prior distribution  $N(\mu, \tau^2)$ . Assume that  $\sigma^2, \mu, \tau^2$  are all known.
- Find the joint probability density function of  $\bar{x} = n^{-1} \sum_{i=1}^n x_i$  and  $\theta$ .
  - Show that the marginal distribution  $m(\bar{x} | \sigma^2, \mu, \tau^2)$  of  $\bar{x}$  is  $N(\mu, (\sigma^2/n) + \tau^2)$ .
  - Derive the posterior distribution  $\pi(\theta | x_1, \dots, x_n)$ .

Sol<sup>n</sup> a) Since  $x_i \sim N(\theta, \sigma^2)$ , the sample mean  $\bar{x}$  is also normally distributed with the same mean but smaller variance  $\sigma^2/n$ .  $\therefore \bar{x} \sim N(\theta, \sigma^2/n)$

$$\therefore p(\bar{x} | \theta) = \frac{1}{\sqrt{2\pi(\sigma^2/n)}} \exp \left\{ -\frac{(\bar{x} - \theta)^2}{2(\sigma^2/n)} \right\}$$

Need to find the joint density function  $p(\bar{x}, \theta)$ .

$$\theta \sim N(\mu, \tau^2) \therefore p(\theta) = \frac{1}{\sqrt{2\pi\tau^2}} \exp \left\{ -\frac{(\theta - \mu)^2}{2\tau^2} \right\}$$

By definition of joint density:

$$p(\bar{x}, \theta) = p(\bar{x} | \theta) p(\theta)$$

$$= \frac{1}{\sqrt{2\pi(\sigma^2/n)}} \exp \left\{ -\frac{(\bar{x} - \theta)^2}{2(\sigma^2/n)} \right\} \cdot \frac{1}{\sqrt{2\pi\tau^2}} \exp \left\{ -\frac{(\theta - \mu)^2}{2\tau^2} \right\}$$

$$\Rightarrow p(\bar{x}, \theta) = \frac{1}{2\pi\sqrt{(\sigma^2/n)^2 + \tau^2}} \exp \left\{ -\frac{1}{2} \left( \frac{(\bar{x} - \theta)^2}{\sigma^2/n} + \frac{(\theta - \mu)^2}{\tau^2} \right) \right\}$$

b) By definition of marginal distribution,  $m(\bar{x} | \sigma^2, \mu, \tau^2) = \int p(\bar{x}, \theta) d\theta$

$$m(\bar{x} | \sigma^2, \mu, \tau^2) = \int_{-\infty}^{\infty} \frac{1}{2\pi\sqrt{(\sigma^2/n)^2 + \tau^2}} \exp \left\{ -\frac{1}{2} \left( \frac{(\bar{x} - \theta)^2}{\sigma^2/n} + \frac{(\theta - \mu)^2}{\tau^2} \right) \right\} d\theta$$

$$= \int_{-\infty}^{\infty} \frac{1}{2\pi\sqrt{(\sigma^2/n)^2 + \tau^2}} \exp \left\{ -\frac{1}{2} \frac{(\bar{x} - \theta)^2}{\sigma^2/n} \right\} \exp \left\{ -\frac{1}{2} \frac{(\theta - \mu)^2}{\tau^2} \right\} d\theta$$

Question assigned to the following page: [3](#)

Ignore this

This expression is the convolution of two normal distributions.

We know that the convolution of two pdf is the distribution of the sum of two random variables whose pdf are involved in the convolution. i.e. if  $x_1 \sim f_1$ ,  $x_2 \sim f_2$ , then  $x_1 + x_2 \sim f_1 * f_2$  where  $*$  is the convolution operator.

We also know that the convolution of two normal pdfs is another normal pdf. i.e. if  $Z_1 \sim N(a_1, b_1^2)$

$$Z_2 \sim N(a_2, b_2^2)$$

$$\text{then } Z_1 + Z_2 \sim N(a_1 + a_2, b_1^2 + b_2^2)$$

Recall that  $p(\bar{x} | \theta) = N(\theta, \frac{\sigma^2}{n})$  or  $\bar{x} \sim N(\theta, \frac{\sigma^2}{n})$

and  $p(\theta) = N(\mu, \tau^2)$  or  $\theta \sim N(\mu, \tau^2)$

$$\begin{aligned} p(\bar{x}, \theta) &= p(\bar{x} | \theta) p(\theta) \\ &= N(\theta, \frac{\sigma^2}{n}) N(\mu, \tau^2) \end{aligned}$$

$$\text{And } \int p(\bar{x}, \theta) d\theta = N(\theta, \frac{\sigma^2}{n}) * N(\mu, \tau^2)$$

By inspecting the previous integral, we can tell that the integration will yield another normal distribution. Hence, if we can find the mean & variance of this new normal distribution, we have all the information.

In general, we want to show that if  $X|Y \sim N(Y, \sigma^2)$  and  $Y \sim N(\mu, \tau^2)$ , then  $X \sim N(\mu, \sigma^2 + \tau^2)$ .

Proof: We assume that we know the distribution of  $X$  is normal.

$$\text{Then } \text{mean}(x) = E[x] = E[E[X|Y]] = E[Y] = \mu$$

$$\text{Var}(X) = E[\text{Var}(X|Y)] + \text{Var}[E[X|Y]] = E[\sigma^2] + \text{Var}(Y) = \sigma^2 + \tau^2$$

Question assigned to the following page: [3](#)

Since  $E(x) = \mu$  &  $\text{mean}(x) = \mu$  &  $\text{Var}(x) = \sigma^2 + \tau^2$  and we assumed that  $x$  is normally distributed, we have

$$X \sim N(\mu, \sigma^2 + \tau^2)$$

Now, in our case, we have  $\bar{x} | \theta \sim N(\theta, \frac{\sigma^2}{n})$  &  $\theta \sim N(\mu, \tau^2)$

$$\therefore f(\bar{x}) = \underbrace{m(\bar{x} | \sigma^2, \mu, \tau^2)}_{N(\mu, \frac{\sigma^2}{n} + \tau^2)} = N(\mu, \frac{\sigma^2}{n} + \tau^2)$$

$\int f(\bar{x}, \theta) d\theta = f(\bar{x}) \leftarrow$  the marginal of  $f(\bar{x}, \theta)$  gives the density of  $f(\bar{x})$  and we know that the density of  $\bar{x}$  is  $N(\mu, \frac{\sigma^2}{n} + \tau^2)$

c) Derive the posterior distribution  $\pi(\theta | x_1, \dots, x_n)$

$$\text{Soln: } \pi(\theta | x_1, \dots, x_n) \propto f(x_1, \dots, x_n | \theta) \pi(\theta)$$

$$\propto \prod_{i=1}^n f(x_i | \theta) \pi(\theta)$$

$$\propto \left( \prod_{i=1}^n \frac{1}{\sqrt{2\pi\sigma^2}} \exp \left\{ -\frac{1}{2\sigma^2} (x_i - \theta)^2 \right\} \right) \cdot \pi(\theta)$$

$$\propto \left( \frac{1}{2\pi\sigma^2} \right)^n \exp \left\{ -\frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \theta)^2 \right\} \cdot \pi(\theta)$$

$$\propto \exp \left\{ -\frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \bar{x} + \bar{x} - \theta)^2 \right\} \cdot \pi(\theta)$$

$$\propto \exp \left\{ -\frac{1}{2\sigma^2} \left( \sum_{i=1}^n (x_i - \bar{x})^2 + \sum_{i=1}^n (\bar{x} - \theta)^2 + 2 \underbrace{\sum_{i=1}^n (x_i - \bar{x})(\bar{x} - \theta)}_{(\bar{x} - \theta) \sum_{i=1}^n (x_i - \bar{x})} \right) \right\} \cdot \pi(\theta)$$

$$\propto \exp \left\{ -\frac{1}{2\sigma^2} \left( \underbrace{\sum_{i=1}^n (x_i - \bar{x})^2}_{\text{independent of } \theta} + n(\bar{x} - \theta)^2 \right) \right\} \cdot \pi(\theta)$$

$$\propto \exp \left\{ -\frac{n}{2\sigma^2} \cdot (\bar{x} - \theta)^2 \right\} \cdot \pi(\theta)$$

$$\propto \exp \left\{ -\frac{n}{2\sigma^2} \cdot (\bar{x} - \theta)^2 \right\} \cdot \frac{1}{\sqrt{2\pi\tau^2}} \exp \left\{ -\frac{(\theta - \mu)^2}{2\tau^2} \right\}$$

$$\propto \exp \left\{ -\frac{n}{2\sigma^2} (\bar{x} - \theta)^2 - \frac{(\theta - \mu)^2}{2\tau^2} \right\}$$

$$\propto \exp \left\{ -\frac{1}{2} \left[ \frac{n}{\sigma^2} (\bar{x} - \theta)^2 + \frac{1}{\tau^2} (\theta - \mu)^2 \right] \right\}$$

Question assigned to the following page: [3](#)

$$\begin{aligned}
 \therefore \pi(\theta | x_1, \dots, x_n) &\propto \exp \left\{ -\frac{1}{2} \left[ \frac{n}{\sigma^2} (\bar{x} - \theta)^2 + \frac{1}{\tau^2} (\theta - \mu)^2 \right] \right\} \\
 &\propto \exp \left\{ -\frac{1}{2} \left[ \frac{n}{\sigma^2} (\bar{x}^2 + \theta^2 - 2\bar{x}\theta) \right. \right. \\
 &\quad \left. \left. + \frac{1}{\tau^2} (\theta^2 + \mu^2 - 2\mu\theta) \right] \right\} \\
 &\propto \exp \left\{ -\frac{1}{2} \left[ \left( \frac{n}{\sigma^2} + \frac{1}{\tau^2} \right) \theta^2 + \underbrace{\left( \frac{n\bar{x}^2}{\sigma^2} + \frac{\mu^2}{\tau^2} \right)}_{\text{indep. of } \theta} \right. \right. \\
 &\quad \left. \left. - 2 \left[ \frac{n}{\sigma^2} \bar{x} + \frac{\mu}{\tau^2} \right] \theta \right] \right\} \\
 &\propto \exp \left\{ -\frac{1}{2} \left[ \underbrace{\left( \frac{n}{\sigma^2} + \frac{1}{\tau^2} \right)}_A \theta^2 - 2 \underbrace{\left[ \frac{n}{\sigma^2} \bar{x} + \frac{\mu}{\tau^2} \right]}_B \theta \right] \right\}
 \end{aligned}$$

This is a normal distribution. We want to know the mean & std.

One could complete the squares but it is easier to find the mode & for normal mean = mode.

$$\begin{aligned}
 \text{Mode} = \operatorname{argmax}_{\theta} A\theta^2 - 2B\theta &= A\left(\theta^2 - \frac{2B}{A}\theta\right) \\
 &= A\left(\theta - \frac{2B}{A}\right)\theta
 \end{aligned}$$

This is a parabola and the peak is the mean of the roots.

The roots are  $\theta = 0$  &  $\theta = \frac{2B}{A}$ , Center =  $\frac{\theta_1 + \theta_2}{2} = \frac{B}{A}$ .

$$\therefore \mu_{\text{posterior}} = \frac{B}{A}$$

Similarly, for a Normal distribution, the coefficient of  $x^2$  is  $-\frac{1}{2\sigma^2}$

$$-\frac{1}{2\sigma_{\text{posterior}}^2} = -\frac{1}{2}A \Rightarrow A = \frac{1}{\sigma_{\text{posterior}}^2} \Rightarrow \sigma_{\text{posterior}} = \frac{1}{A}.$$

$$\therefore \pi(\theta | x_1, \dots, x_n) = N\left(\mu_{\text{posterior}}, \sigma_{\text{posterior}}\right)$$

$$\text{where } \mu_{\text{posterior}} = \frac{\frac{n}{\sigma^2} \bar{x} + \frac{\mu}{\tau^2}}{\frac{n}{\sigma^2} + \frac{1}{\tau^2}} \quad \& \quad \sigma_{\text{posterior}} = \sqrt{\frac{1}{\frac{n}{\sigma^2} + \frac{1}{\tau^2}}}$$
