Problem 1 : (Best Unbissed estimatores, 20pts)

1. Let  $X_1 - X_n$  be rid Poisson Random variables with parameter 1 > 0. Find the UMVUE for (i)  $e^{-\lambda}$  (ii)  $\lambda e^{-\lambda}$ .

Solution: Poisson v. V. X:~ 1k!

| Kle know that  $T = \sum_{i=1}^{n} X_i$  is a complete sufficient statistic for  $\lambda$ .

Also T is poisson  $(n\lambda)$ 

By Lehmann-Scheffe theorem, UMVUE for any parameter  $\theta(\lambda)$  can be obtained by first finding an unbiased estimator U of  $\theta(\lambda)$  and then conditioning that estimator on T to get  $\hat{\theta} = \mathbb{E}[UIT]$  which is UMVUE.

(i) We need to find a statistic U for  $e^{-\lambda}$ . Since  $x_i$  are i.i.d 4  $x_i \sim \frac{\lambda^k e^{-\lambda}}{k!}$ , if we take k=0, we get  $P(x_i=0)=\frac{\lambda^0 e^{-\lambda}}{0!}=e^{-\lambda}$ .

So we can pick any particular  $i \in [0, n]$  of U = I[X; = 0]. Let us pick i = 1 for simplicity. Then V = I[X; = 0].

U is an unbiased estimates of  $e^{-t}$  because  $E[U] = P(X_1 = 0) = e^{-t}$ .

To get UMVVE, we take the conditional expectation E[U|T] where

T is a complete sufficient statistics. We know  $T = \hat{\Sigma}[X_1]$  is complete.  $E[U] = P(X_1 = 0) = e^{-t}$ .

 $E[U|T=t] = \sum_{u} u p(u|T=t) = 0 \cdot p(u=0|T=t) + 1 \cdot p(u=1|T=t)$   $= p(u=1|T=t) = p(x_1=0|T=t)$ 

Now 
$$P(X_1 = 0 \mid T = t) = P(X_1 = 0 \mid X_1 X_2 + \cdots \times_n = t)$$

$$= \frac{P(X_1 = 0, X_2 + X_3 + \cdots + X_n = t)}{P(X_1 + X_2 + \cdots + X_n = t)}$$

$$= \frac{P(X_1 = 0, P(X_2 + X_3 + \cdots + X_n = t)}{P(X_1 + X_2 + \cdots + X_n = t)}$$

$$= \frac{P(X_1 = 0) P(X_2 + X_3 + \cdots + X_n = t)}{P(X_1 + \cdots + X_n = t)}$$

$$= \frac{e^{-1} \lambda^0}{0!} \cdot \frac{e^{-(n-1)\lambda} [n-1]^{\frac{1}{2}}}{\frac{1}{2}!}$$

$$= \frac{e^{-1} \lambda^0}{0!} \cdot \frac{e^{-(n-1)\lambda} (n-1)^{\frac{1}{2}}}{\frac{1}{2}!}$$

$$= \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{-(n-1)\lambda} (n-1)^{\frac{1}{2}}}{\frac{1}{2}!}$$

$$= \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{-1} \lambda^0}{n!}$$

$$= \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{-1} \lambda^0}{n!}$$

$$= \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{-1} \lambda^0}{n!}$$

$$= \frac{e^{-1} \lambda^0}{n!} \cdot \frac{e^{$$

(ii) Now we want to find the UMVUE for (ii) Let Inle can see, just like in (i), P(X,=1) = e 1 = let So we can just take U = I[x,=1] Such that E[U] = P(x1=1) = Le-1 which makes U an unbiased estimators of he-1. We can do the same thing we did in the previous part. E[UlT=t] = Zup(u=vlT=t) = 1. p(u=1/T=t) + 0. p(u=0/T=t) = p(u=1/T=t) The event U=1 is some as the event x1=1.  $E[U|T=t] = p(u=1|T=t) = p(x_1=1|T=t)$  $= \frac{P(X_1=1, T=t)}{P(T=t)} = \frac{P(X_1=1, X_1+X_2+\cdots X_n=t)}{P(T=t)}$  $= \frac{P(x_1=1, x_2+x_3+\cdots x_n=t-1)}{P(x_1+x_2+\cdots +x_n=t)}$ P(X1=1) P(X2+X3+ ... Xn=+-1)  $P(X_1+X_2+\cdots X_n=t)$  $\frac{x^{2}e^{-\lambda}}{1!} \cdot \frac{e^{(n-1)\lambda}}{(t-1)!} \frac{[(n-1)\lambda]^{t-1}}{(t-1)!} = \frac{1}{\lambda} e^{-\lambda} e^{-(x-1)\lambda} \frac{[(n-1)^{t-1}t^{-1}]}{(n-1)!}$ = = = nt nt 1t. (t-1)!  $\frac{e^{-n\lambda} (n\lambda)^{t}}{t!}$ 

$$= \frac{\lambda \cdot (n-1)^{t-1} \cdot t^{t-1}}{n^{t} \cdot x^{t}} = \frac{\lambda \cdot (n-1)^{t-1} \cdot t^{t-1}}{n^{t} \cdot x^{t}}$$

$$= \frac{t}{n} \cdot (\frac{n-1}{n})^{t-1} = \frac{t}{n-1} \cdot (\frac{n-1}{n})^{t}$$

$$= \frac{T}{n} \cdot (\frac{n-1}{n})^{T-1} = \frac{T}{n-1} \cdot (\frac{n-1}{n})^{T}$$
where  $T = \sum_{i=1}^{n} x_{i}$  is the best unbiased estimator i.e. UMVUE

egumani i.e. Univoe

2. Let X1,...- Xn be i.i.d N(M, T2).

Find the best unbiased estimator of TP, where p is a known positive constant, not necessarily an integer.

Spin: Let us layout a Sketch.

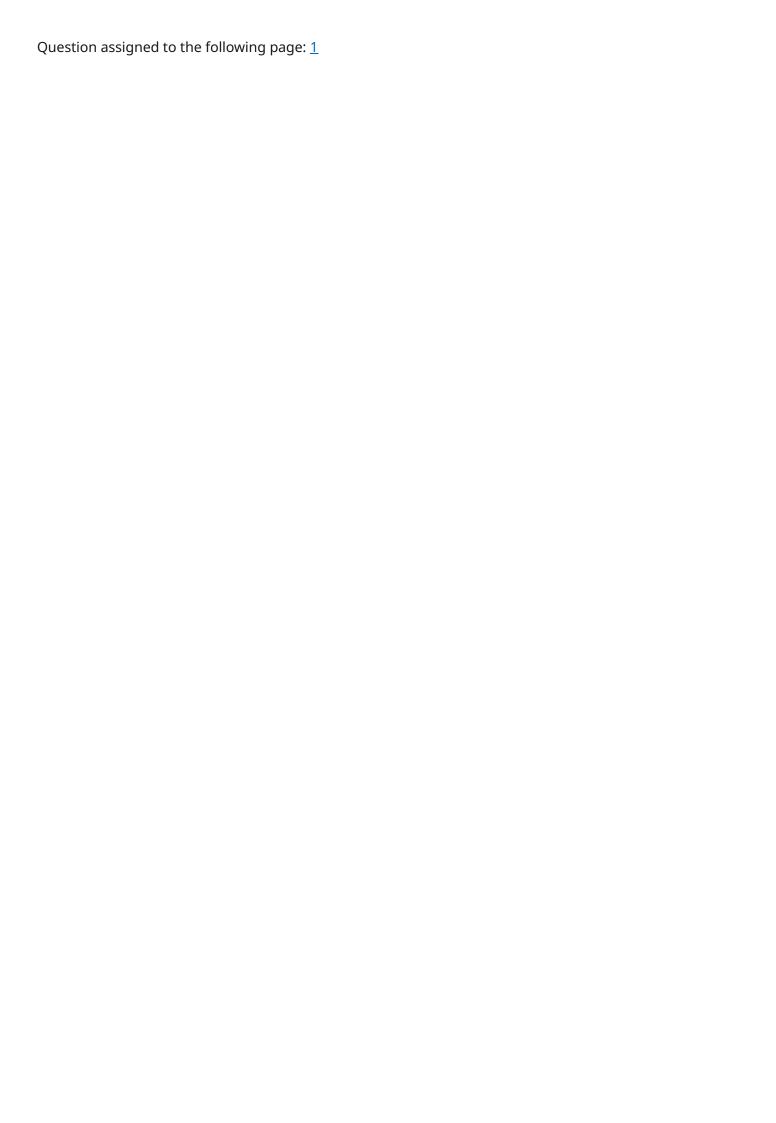

If T is a complete Sufficient statistic for  $\theta$ , then g(T) is complete sufficient for  $g(\theta)$  for bijective g.

Since  $S^2 = \frac{1}{N-1} \sum_{i=1}^{\infty} (X_i - \overline{X})^2$  is complete for  $T^2$ ,

by Lehman Schellé theorem, use need to find an unbiased estimator U for JP that is a function of S2.

When know that  $E[Y^{8}] = 2^{8} \frac{\Gamma(\frac{k}{2}+\gamma)}{\Gamma(\frac{k}{2})}$  if  $Y \sim \frac{2}{\chi_{2k}}$  with k degrees of freedom.

The car probably look for a frequent involving (52) 1/2.

Let 
$$Y = (S^2)^{\frac{1}{2}}$$
. Then  $Y \approx X_{n+1}^2$   

$$(S^2)^{\frac{1}{2}} = (T^2 Y)^{\frac{1}{2}} = T^2 Y^{\frac{1}{2}} = T^2 Y^{\frac{1}{2$$

This has expectation equal to  $\sigma^P$ .

i.e.  $E[Z] = \sigma^P + \Delta$  this is UMVUE as it is a function of  $S^2$  which is a complete statistic for  $\sigma^2$ .

## Problem 2 (Loss function optimality, 20pts)

1. Show that if X is a continuous orandom variable, then min E[X-a]=|E[X-m]| where m is the median of X.

Sol": The median 'm' is that value where the comulative distribution function becomes  $\frac{1}{2}$  i.e.  $F(m) = \frac{1}{2}$ .

Let  $g(a) = E|x-a| = \int_{-\infty}^{\infty} |x-a| f(x) dx$ where f(x) = probability density function of <math>F'(x) = f(x).  $g(a) = \int_{-\infty}^{a} |x-a| f(x) dx + \int_{a}^{-\infty} |x-a| f(x) dx.$   $|x-a|=\begin{cases} a-x; & x < a \\ x-a; & n > a \end{cases}$ 

 $g(a) = \int_{-\infty}^{a} (a-x) f(x) dx + \int_{a}^{+\infty} (a-a) f(x) dx$ 

At any minimum of g(a), g'(a) must change Sign from -ve to +ve going through zero. ine. g'(a)=0

 $g'(\mathbf{a}) = \frac{d}{da} \int_{-\infty}^{a} (a-x)f(x)dx + \int_{a}^{\infty} (a-a)f(x)dx$   $= \int_{-\infty}^{a} (+1)f(x)dx + \int_{a}^{\infty} (-1)f(x)dx$ 

 $= \int_{\infty}^{a} f(x) dx - \int_{a}^{+\infty} f(x) dx$ 

$$\int g'(a) = F(a) - (1 - F(a)) = 2F(a) - 1$$
Setting  $g'(a) = 0$ ,  $2F(a) - 1 = 0$  =>  $F(a) = \frac{1}{2} \Rightarrow a = m$ .

Let  $X_1$ ... $X_n$  be a random sample from  $N(\theta, t^2)$  where  $t^2$  is known. Consider estimating  $\theta$  using Squareed errors loss. Let  $T(\theta)$  be a  $N(\mu, z^2)$  prior distribution on  $\theta$  and  $S^T$  be the Bayes estimator of  $\theta$ . Prove the following holds:

a) For any constant a,b, the estimator  $\delta(x) = aX + b$  has risk function  $R(b,\delta) = a^2 \frac{d^2}{d} + (b-(1-a)\theta)^2$ 

Sol': - 
$$R(\theta, \delta) = E_{x} [(\delta(x) - \theta)^{2}]$$
  
=  $E_{x} [(\alpha \overline{x} + b - \theta)^{2}]$ 

 $= \mathbb{E}_{\mathbf{x}} \left[ \left\{ \mathbf{a}(\mathbf{x} - \mathbf{\theta}) + \mathbf{b} + (\mathbf{a} - \mathbf{i}) \mathbf{\theta} \right\}^{2} \right]$ 

 $= \mathbb{E}_{x} \left[ a^{2} (\bar{x} - \theta)^{2} + \{b + (a - 1)\theta\}^{2} + 2 a(\bar{x} - \theta)(b + (a - 1)\theta) \right]$ 

 $=\frac{2}{a}EC(x-0)^{2}]+[b+(a-1)\theta]^{2}+2a[b+(a-1)\theta]E[x-\theta]$ 

= a2 Var(x) + [b+(a-1)0]2+ 0

 $= a^2 \int_{0}^{2} + \left[b + (a-1)\theta\right]^2$ 

b) Let 
$$\eta = \frac{\sigma^2}{nz^2 + r^2}$$
. The risk function for the Bayes estimator is  $R(\theta, \delta^{T}) = (1 - \eta)^2 \frac{\tau^2}{n} + \eta^2 (\theta - \mu)^2$ 

Solf  $R(\theta, \delta^{T}) = E[(\delta^{T}(x) - \theta)^2]$ 

$$\pi(\theta|\bar{x}) \propto L(\theta;\bar{x}) \pi(\theta)$$

$$\frac{\partial post}{\partial r} = \frac{\left(\frac{n}{\sqrt{r^2}}\right) \times + \frac{M}{Z^2}}{\frac{n}{\sqrt{r^2}} + \frac{1}{Z^2}}$$

$$\sigma_{post} = \frac{1}{\frac{n}{\sigma^2} + \frac{1}{z^2}}.$$

$$\sum_{x=1}^{n} \left( x \right) = \theta p s s + \frac{n}{\sigma^2} + \frac{\mu}{z^2}$$

$$= \frac{n/\sigma^2}{n/\sigma^2 + \frac{1}{2}} \times + \frac{1/2^2}{\frac{n}{2} + \frac{1}{2}} \mu = (1 - n) \times + n \mu$$

$$\mathcal{E}^{T}(x) = (1-n)\overline{x} + n\mu$$

$$\mathcal{R}(\theta, \delta^{T}) = \overline{\mathcal{E}}[(-n)\overline{x} + n\mu - \theta]^{2} = \overline{\mathcal{E}}[(\delta^{T} - 0)^{2}]$$

$$= \overline{\mathcal{E}}[(1-n)(\overline{x} - \theta) + n(\mu - \theta)]^{2}$$

$$= \overline{\mathcal{E}}[(1-n)^{2}(\overline{x} - \theta)^{2} + 2n(1-n)(\overline{x} - \theta)(\mu - \theta)$$

$$+ n^{2}(\mu - \theta)^{2}]$$

$$= (1-n)^{2} \overline{\mathcal{E}}[(\overline{x} - \theta)^{2}]$$

$$+ 2n(1-n)(\mu - \theta) \overline{\mathcal{E}}[\overline{x} - \theta]$$

$$= (1-n)^{2} \frac{\sigma^{2}}{n} + n^{2}(\mu - \theta)^{2}$$

$$= (1-n)^{2} \frac{\sigma^{2}}{n} + n^{2}(\mu - \theta)^{2}$$

$$= (1-n)^{2} \frac{\sigma^{2}}{n} + n^{2}(\mu - \theta)^{2}$$

c) The Bayes risk of the Bayes estimators is  $B(\pi, \delta^{\pi}) = z^2 n$ .

Solo 
$$B(\pi, \overline{\xi}) = \int R(\theta, \xi) d\pi(\theta)$$
  
where  $R(\theta, \xi) = E_{\theta} [(\xi(x) - \theta)^{2}]$ 

$$B(T, \vec{\delta}) = \int (1-n)^2 \frac{d^2}{n} + n^2 (N-\theta)^2$$

$$= (1-n)^2 \frac{d^2}{n} + n^2 \int (\theta-N)^2 dT(\theta)$$

$$= (1-n)^2 \frac{d^2}{n} + 2^2 n^2$$

$$= (1-n)^2 \frac{d^2}{n} + 2^2 n^2$$

$$B(\pi, s^{m}) = (1-\eta)^{2} \frac{\sigma^{2}}{n} + Z^{2} \eta_{s}^{2}$$
on Simplification, this give us  $Z^{2}\eta$ .

$$\frac{\sigma^{2}}{n} (1-n)^{2} = \frac{n^{2}z^{2}}{(nz^{2}+\sigma^{2})^{2}} \cdot \frac{\sigma^{2}}{n}$$

$$= \frac{nz^{2} \cdot \sigma^{2}}{(nz^{2}+\sigma^{2})^{2}}$$

Problem 3: (EM algorithm, 20 pts) For each i=1, .... n, define the indicator Yi = I { X; > C;} where G,....
